① solve the following recurrence relation.

a) $x(n)=x(n-1)+5$ for $n>1$ with $x(1)=0$

i) write down the first two terms to identify the pattern.

$x(1)=0$

$x(2)=x(1)+5=5$

$x(3)=x(2)+5=10$

$x(4)=x(3)+5=15$

ii) identify the pattern for the general term

→ The first term $x(1)=0$

The common difference $d=5$

The general formula for the n^{th} term of an AP is.

$$x(n)=x(1)+(n-1)d$$

substituting the given values

$$x(n)=0+(n-1)\cdot 5=5(n-1)$$

The solution is

$$x(n)=5(n-1)$$

b) $x(n)=3x(n-1)$ for $n>1$ with $x(1)=4$

i) write down the first two terms to identify the pattern

$x(1)=4$

$x(2)=3x(1)=3\cdot 4=12$

$x(3)=3x(2)=36$

$x(4)=3x(3)=108$

ii) identify the general term.

→ The first term $x(1)=4$

→ The common ratio $r=3$

The general formula for the n^{th} term of a GP is

$$x(n)=x(1)\cdot r^{n-1}$$

substituting the given values

$$x(n) = 4 \cdot 3^{n-1}$$

The solution is

$$x(n) = 4 \cdot 3^{n-1}$$

c) $x(n) = x(n/2) + n$ for $n > 1$ with $x(1) = 1$ (solve for $n = 2^k$)

For $n = 2^k$, we can write recurrence in terms of k.

1) substitute $n = 2^k$ in the recurrence

$$x(2^k) = x(2^{k-1}) + 2^k$$

2) write down the first few terms to identify the pattern.

$$x(1) = 1$$

$$x(2) = x(2^1) = x(1) + 2 = 1 + 2 = 3$$

$$x(4) = x(2^2) = x(2) + 4 = 3 + 4 = 7$$

$$x(8) = x(2^3) = x(4) + 8 = 7 + 8 = 15$$

3) Identify the general term by finding the pattern

we observe that:

$$x(2^k) = x(2^{k-1}) + 2^k$$

we sum the series:

$$x(2^k) = 2^k + 2^{k-1} + 2^{k-2} + \cdots$$

since $x(1) = 1$:

$$x(2^k) = 2^k + 2^{k-1} + 2^{k-2} + \cdots$$

The geometric series with the term $a = 2$ and the last term 2^k except for the additional $+1$ term.

The sum of a geometric series is with ratio $r = 2$ is given by

$$S = \frac{a(r^n - 1)}{r - 1}$$

Here $a = 2$, $r = 2$ and $n = k$:

To determine the recurrence relation for the algorithm's basic operation count, let's analyze the steps involved in the algorithm. the basic operation are the comparisons and function calls.

Recurrence relation setup.

1) Base case when n=1, the algorithm performs a single operations to return A[0].

2) Recursive case when n>1, the algorithm:

makes a recursive call to min(A[0..n-2]):

Performs a comparison b/w temp and A[n-1]

Let T(n) represent the no. of basic operation the algorithm performs for an array of size n.

1) Base case:

$T(1)=1$

2) Recursive case

$T(n)=T(n-1)+1$

Here T(n-1) accounts for the operations performed by the recursive call to min[A[0..n-2]]: and the +1 accounts for the comparison b/w temp and A[n-1]

To solve this recurrence relation we can use iteration method:

$T(n)=T(n-1)+1$

$=(T(n-2)+1)+1$

$=((T(n-3)+1)+1)+1$

$=\cdots$

$=1+(n-1)$

$=n$

(2) Evaluate the following recurrences complexity.

i) $T(n) = T(n/2) + 1$, where $n = 2^k$ for all $k \geq 0$.

The recurrence relation can be solved using iteration method

i) substitute $n = 2^k$ in the recurrence

2) iterate the recurrence

for $k=0$: $T(2^0) = T(1) = T(1)$

$k=1$: $T(2^1) = T(1) + 1 =$

$k=2$: $T(2^2) = T(8) = T(n) + 12 (T(1)+2) + 1 = T(1) + 2$

$k=3$: $T(2^3) = T(8) = T(n) + 1 = (T(1)+2) + 1 = T(1) + 3$

3) generalize the Pattern

$T(2^k) = T(1) + k$

since $n = 2^k$, $k = \log_2 n$:

$T(n) = T(2^k) = T(1) + \log_2 n$

4) Assume $T(1)$ is a constant C.

$T(n) = C + \log_2 n$

The solution is

$T(n) = O(\log n)$

ii) $T(n) = T(n/3) + T(2n/3) + cn$ where c is constant and n is input size.

The recurrence can be solved using the master's theorem for divide-and-conquer recurrence of the form:

$T(n) = aT(n/b) + f(n)$

where $a = 2, b = 3$ and $f(n) = cn$.

Lets determine the value of $\log_b a$:

$\log_b a = \log_3 2$

using the properties of logarithms

$$\log_3 2 = \frac{\log 2}{\log 3}$$

Now we compare $f(n) = cn$ with $n^{\log_3 2}$:

$f(n) = O(n)$

$n = n^1$

since $\log_3 2$ we are in the third case of the master's theorem.

$f(n) = O(n^c)$ with $c > \log_b a$

The solution is:

$T(n) = O(f(n)) = O(cn) = O(n)$

(3) consider the following recurrence algorithm?

min [A[0---- n-2]]
if n=1 return A[0]
else temp = min(|A|0---n-2])
if temp <= A(n-1) return temp
else
Return A[n-1]

a) what does this algorithm compute?

The given algorithm, min[A[0,----n-1]) computes the minimum value in the array 'A' from index '0' for 'n-1'. if does this by recursively finding the minimum value in the sub array A[0----n-2] and then comparing it with the last element 'A[n-1] to determine the overall maximum value.

b) setup a recurrence relation for the algorithm basic operation count and solve it.

the algorithms involved in parisons

The solution is
$T(n) = n$

This means the algorithm performs n basic operations for an input array of size n.

(4) Analyze the order of growth

i) $f(n) = 2n^2+5$ and $g(n) = 7n$ use the $\Omega(g(n))$ notation.

To analyze the order of growth and use the Ω notation, we need to compare the given function $F(n)$ and $g(n)$.

given functions:

$F(n) = 2n^2+5$

$g(n) = 7n$

Order of growth using $\Omega(g(n))$ notation:

The notation $\Omega(g(n))$ describes a lower bound on the growth rate that for sufficiently large n, $F(n)$, grows at least as fast as $g(n)$

$$F(n) \geq c \cdot g(n)$$

Lets analyze $F(n) = 2n^2+5$ with respect to $g(n) = 7n$

1) identify Dominant terms:

→ The dominant terms in $F(n)$ is $2n^2$ since it grows faster then the constant terms as n increases.

→ The dominant term in $g(n)$ is $7n$.

2) establish the inequality:

→ We want to find constants c and n_0 such that:

$$2n^2+5 \geq c \cdot 7n \text{ for all } n \geq n_0$$

3) simplify the inequality:
